

## Practice Guidelines

# SGLT-2 Inhibitors and GLP-1 Receptor Agonists in Type 2 Diabetes: BMJ Rapid Recommendation

### Key Points for Practice

- To reduce overall mortality in patients with type 2 diabetes mellitus, the BMJ/MAGIC Group recommends prescribing SGLT-2 inhibitors in those with cardiovascular disease and/or chronic kidney disease or three or more risk factors for cardiovascular disease.
- GLP-1 receptor agonists are reasonable alternatives to SGLT-2 inhibitors in patients with similar risk profiles because this drug class also improves mortality, although to a lesser extent.
- Although SGLT-2 inhibitors and GLP-1 receptor agonists do not increase the risk of severe hypoglycemia, SGLT-2 inhibitors increase the risk of genital infections, and GLP-1 agonists have gastrointestinal adverse effects, especially at initiation and with high doses.

From the AFP Editors

**Management of patients** with type 2 diabetes mellitus is evolving. Instead of focusing on how treatment affects markers of glycemic control, which has not shown benefit, treatments should be based on anticipated reductions in cardiovascular and kidney disease outcomes. Sodium-glucose cotransporter 2 (SGLT-2) inhibitors and glucagon-like peptide 1 (GLP-1) receptor agonists demonstrate consistent risk reductions for mortality, myocardial infarction, stroke, heart failure, and renal outcomes, irrespective of their effects on glycemia. The BMJ/MAGIC Group performed a systematic review to determine which patients may benefit from SGLT-2 inhibitors or GLP-1 receptor agonists.

### Guideline Applicability

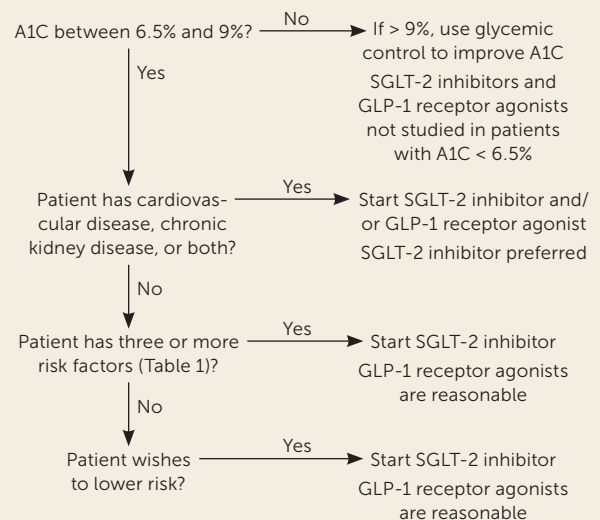

This guideline applies to patients with A1C values between 6.5% and 9%. Patients with A1C greater than 9% are at risk of

life-threatening severe hyperglycemia and outcomes such as retinopathy, neuropathy, and diabetic ulcers; these patients may benefit from an emphasis on glycemic control. Because trials in the systematic review included only patients with A1C of 6.5% or greater, the benefits of these medications in patients with lower values are unknown. *Figure 1* is an algorithm based on the guideline.

### SGLT-2 Inhibitors

The BMJ/MAGIC Group strongly recommends that SGLT-2 inhibitors be added to existing treatment for all patients with type 2 diabetes, cardiovascular disease, and chronic kidney disease. In these very high-risk patients, SGLT-2 inhibitors reduce overall mortality with a number needed to treat (NNT) of 25 (95% CI, 18 to 48) over five years. SGLT-2 inhibitors reduce mortality in lower-risk patients, although absolute benefits are smaller. For patients with

cardiovascular disease but not chronic kidney disease, SGLT-2 inhibitors reduce overall mortality with an NNT of 39 (95% CI, 27 to 72) over five years. Patients with chronic kidney disease but not cardiovascular disease have an NNT of 56 (95% CI, 40 to 100) over five years. For patients who do not have chronic kidney disease or cardiovascular disease but have at least three risk factors from *Table 1*, SGLT-2 inhibitors decrease mortality with an NNT of 100 (95% CI, 67 to 167) over five years. For patients in these risk groups, adding an SGLT-2 inhibitor should be considered.

In low-risk patients with less than three risk factors, SGLT-2 inhibitors still improve mortality, but absolute benefits are small. For patients who wish to reduce their cardiovascular and renal risk, SGLT-2 inhibitors are reasonable.

SGLT-2 inhibitors do not increase the risk of hypoglycemia severe enough to require treatment, but their use is associated with an increased risk of vaginitis and balanitis, especially in patients with a history of these conditions. SGLT-2 inhibitors increase the risk of genital infections, with a number needed to harm (NNH) of 7 (95% CI, 6 to 9) over five years. They may be associated with a slightly increased risk of diabetic ketoacidosis, even in patients with normal glucose levels.

### GLP-1 Receptor Agonists

GLP-1 receptor agonists improve mortality but to a lesser extent than SGLT-2 inhibitors. SGLT-2 inhibitors are superior to GLP-1 receptor agonists in improving cardiovascular and renal outcomes, except for nonfatal stroke.

The BMJ/MAGIC Group suggests GLP-1 receptor agonists as an alternative to SGLT-2 inhibitors for patients with type 2 diabetes, cardiovascular disease, and chronic kidney disease. In these very high-risk patients, GLP-1 receptor agonists reduce overall mortality, with an NNT of 42 (95% CI, 29 to 84) over five years.

GLP-1 receptor agonists reduce mortality in lower-risk patients, although absolute benefits are smaller. For patients with cardiovascular disease but not chronic kidney disease, GLP-1 receptor agonists reduce overall mortality, with an NNT of 59 (95% CI, 40 to 112) over five years. In patients with chronic kidney disease but not cardiovascular disease, the NNT is 77 (95% CI, 56 to 167) over five years.

Although GLP-1 receptor agonists improve mortality in low-risk patients, the absolute

**TABLE 1**

### Risk Factors That Increase Benefit of SGLT-2 Inhibitors and GLP-1 Receptor Agonists

Male sex  
Asian, African, or Hispanic ethnicity  
Age > 60 years  
Family history of cardiovascular or kidney disease  
A1C  $\geq$  6.5%  
Current smoker  
Uncontrolled hypertension ( $\leq$  140/90 mm Hg)  
Dyslipidemia (total cholesterol  $\geq$  200 mg per dL [5.18 mmol per L] or HDL cholesterol < 39 mg per dL [1.01 mmol per L])

GLP-1 = glucagon-like peptide 1; HDL = high-density lipoprotein; SGLT-2 = sodium-glucose cotransporter 2.

benefits are very small. For patients who wish to reduce their cardiovascular and renal risk, SGLT-2 inhibitors are preferred, but GLP-1 receptor agonists are reasonable.

Like SGLT-2 inhibitors, GLP-1 receptor agonists do not increase the risk of hypoglycemia severe enough to require treatment, but their use can cause gastrointestinal symptoms (NNH = 18; 95% CI, 8 to 112), especially at the beginning of treatment and at high doses.

### Shared Decision-Making

Although SGLT-2 inhibitors are more effective than GLP-1 receptor agonists, benefits are similar. Prescribing choices should be based on patient preferences, medication adverse effects, and cost.

SGLT-2 inhibitors require monitoring for dizziness, hypotension, and renal dysfunction within three months of initiation and are contraindicated when glomerular filtration rate is reduced, usually to less than 30 mL per kg per 1.73 m<sup>2</sup>. Although SGLT-2 inhibitors increase the risk of genital infections, they do not appear to increase rates of Fournier gangrene or amputations. Tolerability to GLP-1 receptor agonists can be limited by gastrointestinal events, and starting at a low dose with slow titration is recommended. GLP-1 receptor agonists cannot be used in combination with dipeptidyl-peptidase 4 inhibitors. Most GLP-1 agonists (except semaglutide) are available only by injection and require storage below 86°F (30°C).

SGLT-2 inhibitors and GLP-1 receptor agonists are associated with similar weight loss. Both can increase the risk of hypoglycemia if used in combination with glinides, insulin, or sulfonylureas but not as monotherapy. The cost of GLP-1 receptor agonists is about two to three times

## PRACTICE GUIDELINES

higher than SGLT-2 inhibitors. Cost was not considered in the recommendations.

**Editor's Note:** The NNTs and NNHs were calculated by the authors based on data in the systematic review.

This BMJ/MAGIC Group guideline is important because it proposes a new paradigm for diabetes therapy. Although we have long known that A1C targets are not effective, this guideline recommends focusing completely on cardiovascular and renal risk as long as A1C is less than 9%. The NNTs for SGLT-2 inhibitors to reduce mortality are truly impressive, although 1 in 7 patients will get an additional genital infection in five years. The systematic review did not show significant increases in Fournier gangrene or amputation despite early reports. GLP-1 receptor agonists are less beneficial and have common gastrointestinal effects, leading to a recommendation for slow dose tapering. Weight loss is similar between drug classes—nearly 2 kg (4 lb, 6 oz) with SGLT-2 inhibitors and 1.5 kg (3 lb, 5 oz) with GLP-1 receptor agonists.

The BMJ/MAGIC Group found that Asian, African, or Hispanic ethnicity was a risk factor for cardiovascular and renal outcomes and increased benefits of the medications, although race and ethnicity are social constructs that may not represent a genetic predisposition.

These recommendations and the systematic review add to the increasing evidence of the importance of these medications.—Michael J. Arnold, MD, Contributing Editor
